

# Spin-orbitals, terms, and wave functions for two-electrons in the 32 crystallographic point groups

Compiled and computed by Juan Lizarazo

November 16, 2021

This tables collect symbolic expressions for the terms of two-electrons under the point group symmetry of the 32 crystallographic point groups.

In the expressions for the wave functions for the various terms under each group the vertical bars denote determinantal states of the two enclosed spin-orbital symbols. If the symbol for a spin orbital is decorated with a top bar that denotes that it has spin down, if not decorated thus then it has spin up. The different wave functions are grouped under headings in red that denote the origin of the wave functions that follow, in the sense of which two irreducible representations gave way to them. Each term may contain more than one basis for the irreducible representation of the term, if this is the case then the several bases can be identified as grouping of wave functions under the same red heading, with the same value for  $M$  and a full collection of component symbols for the irreducible representation of the term.

The provided expressions for the wave functions are eigenvectors of  $S^2$ ,  $S_z$ , and together with the adequate other wave functions in the term form bases for the corresponding irreducible representation. The "z-axis" here may be taken as any axis that is convenient to choose according to the symmetries of the different groups.

For the electronic access to these tables, an electronic version is provided in the GitHub repository for `qdef` in the file `./Data/2e-terms.pkl`. It consists of a python dictionary whose keys are labels for the different groups, and whose values are `qdefcore.Term` objects that include symbolic expressions for the wave functions as well as additional information for the corresponding term.
